

# RTH010

## 9 GHz Bandwidth 1 GS/s Dual Track-and-Hold

### Features

- ◆ 9 GHz Input Bandwidth (0.25 Vpp  $V_{IN}$  Differential)
- ◆ 100 - 1000 MHz Sampling Rate (TH1)
- ◆ 100 - 1000 MHz Output Data Rate (TH2)
- ◆ -70 dB Hold Mode Distortion (1.0 GHz 0.25 Vpp  $V_{IN}$  Differential)
- ◆ -50 dB Hold Mode Distortion (1.0 GHz 0.25 Vpp  $V_{IN}$  SE)
- ◆ -52 dB Hold Mode Distortion (4.0 GHz 0.25 Vpp  $V_{IN}$  Differential)
- ◆ -42 dB Hold Mode Distortion (4.0 GHz 0.25 Vpp  $V_{IN}$  SE)
- ◆ < 50 fs Aperture Jitter
- ◆ < 250 ps Acquisition Time
- ◆ < 50 ps Rise Time (20 - 80%)
- ◆ Differential Analog Input/Output
- ◆ Output Held more than Half Clock Cycle
- ◆ Track Mode Select

Figure 1. Functional Block Diagram

### Product Description

RTH010's bandwidth and aperture jitter enable 1 GS/s accurate sampling of DC to multi-GHz signals. The differential-to-differential dual track-and-hold cascades two track-and-hold circuits, TH1 and TH2. The RTH010 provides a held output for more than half a clock cycle, easing

bandwidth requirements of subsequent circuitry relative to the case of a single track-and-hold (TH). The option to independently clock TH1 and TH2 further relaxes this requirement for sub-sampling applications.

### Ordering information

PART NUMBER	DESCRIPTION	<p><b>CAUTION</b></p> <p>DEVICE SUSCEPTIBLE TO DAMAGE BY ELECTROSTATIC DISCHARGE (ESD)</p> 
RTH010-QC	24 Pin QFP Package	
RTH010-DI	Die	
EVRTH010-QC	Evaluation Board with a RTH010-QC	

## ***Absolute Maximum Ratings***

### **Supply Voltages**

VCC to GND .....	-1 to +6 V
VEE to GND .....	-6 to +1 V
VCC to VEE .....	-1 to +11 V

### **Input Voltages**

INP, INN to GND .....	-1 to +1 V
CLK1P, CLK1N, CLK2P, CLK2N to GND .....	-1 to +1 V
TMS to GND .....	-6 to +1 V

### **Output Voltages**

Vterm (Output Termination Voltage) to GND.. -2.5 to +0.5V

### **Temperature**

Case Temperature .....	-15 to +85 °C
Junction Temperature .....	+125 °C
Lead, Soldering (10 Seconds) .....	+220 °C
Storage .....	-40 to 125 °C

## DC Electrical Specification

Test Conditions (see notes for specific conditions): Room Temperature; VCC = 5V; VEE = -5.2V; Clocks: 1GHz, 0.6Vpp Differential; Input: 250mV Single-Ended; Outputs Terminated Into 50  $\Omega$  to 0V.

	PARAMETER	SYMBOL	CONDITIONS, NOTE	MIN	TYP	MAX	UNITS

16.2	Recovery Time		Required Accumulated Track Time After thold2,max Violation			4	ns

<sup>1</sup> The clock source jitter and the aperture jitter combine in an rms manner to yield the total sampling jitter. See Definition of Terms.  
<sup>2</sup> Device aperture jitter increases as the V(CLK1P) – V(CLK1N) slew rate at the zero crossing decreases. See Theory of Operation.  
<sup>3</sup> The differential pedestal error is proportional to the input signal. This gain loss may be observed at the DTH output if TH2 is in track mode during the TH1 track to hold transition.  
<sup>4</sup> The variance of the hold noise is proportional to the hold time, thold. TH1 and TH2 hold noise, up to the output sampling instant, should be RMS added to the hold mode integrated noise of the DTH.  
<sup>5</sup> Maximum hold time is determined by droop of single-ended hold capacitor voltages. The resulting shift of internal operating voltages is not directly observable at the DTH outputs but eventually causes device performance degradation.  
<sup>6</sup> TH1 tacq, dvdt,max, and tr also apply to the reconstructed DTH output if sub-sampling a fast-edge repetitive wave form.  
<sup>7</sup> Output is settled ta2 + ts2 after CLK2(P/N) downward transition.  
<sup>8</sup> The differential pedestal error is proportional to the input signal..

<b>22.0</b>	<b>POWER SUPPLY REQUIREMENTS</b>						
22.1	Positive Supply Voltage	VCC		4.75	5.0	5.25	V
22.2	Negative Supply Voltage	VEE		-5.45	-5.2	-4.95	V
<b>23.0</b>	<b>OPERATING TEMPERATURE<sup>10</sup></b>						
23.1	Case Temperature	T <sub>c</sub>	Measured at Bottom Plate	-15		85	°C
23.2	Junction Temperature	T <sub>j</sub>				125	°C

<sup>9</sup> For > 500 MHz sinusoidal CLK1(P/N), 500 to 700 mVpp amplitude is recommended for combined aperture jitter and clock feed-through performance. At lower clock frequencies, use high amplitude for minimum jitter. See Theory of Operation.

<sup>10</sup> The part is designed to function within a junction temperature range of -40 ~ 125°C. For the best performance, operation within the specified temperature range with a proper heatsink attached to the device is recommended. The heatsink should be attached to the bottom of the PCB, on a metal pad connect by thermal vias to the metal pad where the part is soldered.

### Pin Description and Pin Out

P/I/O	NAME	FUNCTION
P	GND	Power Supply Ground
P	VCC	Positive Power Supply, +5.0V
P	VEE	Negative Power Supply, -5.2V
I	CLK1P	Clock 1 Input: High = TH1 in Track Mode Low = TH1 in Hold Mode
I	CLK1N	Complementary Clock 1 Input
I	CLK2P	Clock 2 Input: High = TH2 in Track Mode Low = TH2 in Hold Mode
I	CLK2N	Complementary Clock 2 Input
I	INP	Analog Input
I	INN	Complementary Analog Input
I	TMS	Track Mode Select: Open = Sampled operation Ground = TH1 and TH2 in Track Mode
O	OUTP	Analog Output
O	OUTN	Complementary Analog Output

Figure 2. RTH010-QC pin configuration (top view, not to scale) 24-lead Quad Flat Package (QFP).

## Definitions of Terms

**Acquisition Time (tacq).** The delay between the time a track-and-hold circuit (TH) enters track mode and the time the TH hold capacitor nodes track the input within some specified precision. The acquisition time sets a lower limit on the required track time during clocked operation.

**Aperture Delay (ta).** The average (or mean value) of the delay between the hold command (input clock switched from hold to track state) and the instant at which the analog input is sampled. The time is positive if the clock path delay is longer than the signal path delay. It is negative if the signal path delay is longer than the clock path delay.

**Aperture Jitter ( $\Delta t$ ).** The standard deviation of the delay between the hold command (input clock switched from track-to-hold state) and the instant at which the analog input is sampled, excluding clock source jitter. It is the total jitter if the clock source is jitter free (ideal). Jitter diverges slowly as measurement time increases because of “1/f” noise, important at low frequencies (< 10 kHz). The specified jitter takes into account the white noise sources only (thermal and shot noise). For high-speed samplers this is reasonable, since even long data records span a time shorter than the time scale important for 1/f noise. For white-noise caused jitter, the clock and aperture jitter can be added in an rms manner to obtain the total sampling jitter.

If the underlying voltage noise mechanism of the sampling jitter has a white spectrum, the sampled signal will display a white noise floor as well. In this case, the required aperture jitter,  $\Delta t$ , to achieve a certain SNR, for a full-scale sinewave at frequency,  $f$ , is given by (B. Razavi, Principles of Data Conversion, IEEE Press, 1995, Appendix 2.1):

$$SNR (dB) = -20 \log(2\pi f \Delta t)$$

If this TH is used in front of an  $n$ -bit ADC, then the ideal ADC SNDR is given by:

$$SNDR (dB) = 10 \log(3/2) + 20 \log(2)^n = 1.76 + 6.02n$$

In order that the TH jitter performance does not limit the ADC performance, the jitter must fulfill:

$$\Delta t \leq \frac{1}{\sqrt{6}\pi 2^n f}$$

Note that this is independent of the sampling rate, so undersampling does not improve jitter tolerance. The averaging that is often combined with undersampling in test equipment does improve jitter tolerance (and tolerance to other white noise effects).

The criterion above is sharper than the standard (incorrect) time-domain slope estimate by a factor  $\sqrt{6}$ . The reason is that  $n$ -bit quantization requires an rms error of (quantization step)/ $\sqrt{12}$ , which is considerably smaller than the quantization step error implicitly allowed in the usual time-domain estimates (another  $\sqrt{2}$  comes from the energy of a sine wave relative to its amplitude squared).

The time-domain maximum slope argument can be appropriate for non-sinusoidal inputs, such as those encountered in instrumentation. If the rms error,  $\Delta V$ , in the maximum slope region, slope FSR/(rise time), is used to define an effective number of bits,  $n$ , then the jitter simply needs to fulfill:

$$\Delta t \leq \frac{\text{rise time}}{2^n}$$

**Clock Jitter.** The standard deviation of the mid-points of the relevant (rising or falling) edge of the clock source relative to the ideal edge (best fit). This jitter can be derived from the phase noise of the clock source, where the lower frequency bound of integration should correspond to the duration of a measurement record that the source will be used for.

**Common-Mode Rejection Ratio (CMRR).** Proportionality coefficient of the differential output and the common mode component of input signal. If an ideal symmetric input is available, CMR is the ratio of the differential output to the input on either input pin. A high-quality 50-ohm splitter may be used to generate the symmetrical inputs.

**Full Scale Range (FSR).** The maximum difference between the highest and lowest input levels for which various device performance specifications hold, unless otherwise noted.

**Gain.** Ratio of output signal magnitude to input signal magnitude. For sinewave inputs, it is the ratio of the amplitude of the first (main) harmonic output (HD1) to the amplitude of the input.

**Input Bandwidth (BW, bw).** The input frequency at which the gain for sinewave input is reduced by 3

dB (factor  $1/\sqrt{2}$ ) relative to its average value at low frequencies. The low frequency range is defined as the range including DC over which the gain stays essentially constant. The high frequency range is characterized by an increase in gain variation versus frequency, at least including the eventual monotonic decrease of the gain ("roll-off"). The input bandwidth tends to be input amplitude dependent. It is normally largest for very small inputs (small signal bandwidth, bw) and smallest for FSR inputs (large signal bandwidth, BW).

**Settling Time (ts).** The delay between the time that a track-and-hold circuit (TH) enters hold mode and the time that the TH hold capacitor nodes settle to within some specified precision. The settling time sets a lower limit on the required hold time during clocked operation.

**Spectrum.** The finite Fourier transform (FFT) of the discrete-time-sampled TH output. Ideally, this is obtained with a very high-resolution ADC quantizing the TH output with a clock rate locked to the TH clock (the ADC may be clocked at a slower rate than the

TH). In the case of a dual TH (DTH), we can also use the beat frequency test, where the input frequency is close to an integer multiple of the clock frequency, and the DTH output is fed directly into a spectrum analyzer. The DTH output then contains little high frequency energy and the low frequency part of the spectrum analyzer sweep accurately represents the TH spectrum that would have been obtained with the ADC method.

**Spurious Free Dynamic Range (SFDR).** The ratio of the magnitude of the first (main) harmonic, HD1, and the highest other harmonic (or non-harmonic other tone, if present), as observed in the TH spectrum. The input is FSR, unless otherwise noted. SFDR in dB is given by  $20\log$  (SFDR as amplitude ratio), and is generally positive.

**Total Harmonic Distortion (THD).** The ratio of the square root of the sum of the harmonics 2 to 5 to the amplitude of the first (main) harmonic in the TH spectrum. THD in dB is given by  $20\log$  (THD as amplitude ratio), and is generally negative.

## Theory of Operation

The DTH chip contains two TH's, TH1 and TH2, in series, together with clock shaping circuitry, BUFFER1 and BUFFER2, and a 50-ohm output driver, OUTBUF (Figure 1). To maximize dynamic range and insensitivity to noise, all non-DC internal circuits and all non-DC inputs and outputs are differential. TH1 determines the dynamic sampled-mode performance of the DTH. Its sampling bridges exploit the ultra-high speed of the Schottky diodes available in the GaAs HBT process. TH1 clock inputs, CLK1P and CLK1N, should be driven by a low-jitter clock source. TH2 is similar to TH1, except that its bandwidth requirement is lower and its gain is closer to unity.

The DTH receives a differential analog input signal at inputs INP and INN, which is sampled on the TH1 hold capacitors upon a falling transition of its differential clock voltage  $V(\text{CLK1P}) - V(\text{CLK1N})$ , after an aperture delay,  $t_a$ , see Figure 3. TH1's aperture delay is positive, nominally 60ps.

The sampling instant is affected by clock source jitter (off-chip) and aperture jitter (caused by on-chip noise). From the Definition of Terms, the required total sampling jitter for sampling a 1 GHz 1 Vpp sine

wave with 10-bit accuracy is 127 fs. The aperture jitter of the RTH010 is less than 100 fs for a 1 GHz 0.5 Vpp TH1 clock, CLK1. Using RMS addition of jitter, the clock source jitter must be less than 80 fs (over the measurement record time) for direct 10-bit sampling of GHz range signals. Given a noise variance,  $\Delta V$ , of the on-chip clock buffer, its aperture jitter,  $\Delta t$ , is inversely proportional to the clock buffer gain and the slew rate of the incoming clock at the zero-crossing point:

$$\Delta t = \frac{\Delta V}{\text{gain} \times \text{slew rate}} .$$

For low slew rates or frequencies, the clock buffer gain is constant and its aperture jitter is inversely proportional to the input clock slew rate, improving with increasing slew rate. For high slew rates or high frequencies, the jitter increases again, because the buffer gain drops steeply. For the RTH010, the clock buffer gain is still roughly constant up to 1 GHz, so that the aperture jitter is inversely proportional with

the slew rate of the incoming clock. In the above equation, we have  $\Delta V/gain \approx 0.15$  mV. The RTH010 aperture jitter at various slew rates can then be estimated. For example, a 1 GHz 0.5 Vpp sinusoidal CLK1 signal corresponds to a slew rate  $\sim 1.6$  V/ns, correctly yielding an aperture jitter  $< 100$  fs.

The held and buffered output of TH1, VTH1, is sampled on the TH2 hold capacitors upon a falling transition of its differential clock voltage  $V(\text{CLK2P}) - V(\text{CLK2N})$ , after an aperture delay closely equal to that of TH1. This allows simple out-of-phase clocking of TH1 and TH2 by having opposite phases for CLK1 and CLK2. Aperture jitter of TH2 is irrelevant, since the slew rate of the TH2 input is equal to the TH1 differential droop rate, about 1000x lower than the input slew rate for TH1 for a 1 GHz 1 Vpp sine wave. TH2 can be in track mode before TH1 switches to hold, but a minimum track time of TH2 after TH1 enters hold mode must be observed to ensure that TH2 has fully acquired the TH1 output ( $t_{\text{track2, min}}$ ).

Hold mode feedthrough, or in to out hold-mode gain in dB, again is important for TH1 and not for TH2, since any distortion on the held TH1 signal by a rapidly varying TH1 input will be sampled by TH2, and can not be removed. RTH010's TH1 hold mode feedthrough performance is more than sufficient for 10 bit sampling of GHz range signals.

After a TH1 postamplifier, TH2 produces an output VTH2. For out-of-phase clocking, the delay from the hold instant of TH1 to the ideal sampling time of circuitry after TH2 is close to one full clock cycle, for example 1 ns at a 1 GHz sampling rate. The TH2

output is flat for more than half a clock cycle, which eases the bandwidth requirement of subsequent circuitry. This is true, even though a small glitch will be present at the transition from track to hold of TH2 and the output is only 10 bit accurate during the latter part of half a clock cycle.

Lower limits for the sampling rates of TH1 and TH2 are set by single-ended hold-mode droop rates, and lead to the specification of maximum hold times ( $t_{\text{hold1, max}}$  and  $t_{\text{hold2, max}}$ ). For longer hold times, the DTH must be allowed sufficient recovery time during track phase (or a sequence of track phases), so it can return to normal operation mode. The bandwidth of subsequent circuitry can be minimal if TH2 is clocked at its lowest recommended frequency, 100 MHz. Since TH1 should be clocked at least at 100 MHz, and possibly faster to meet jitter requirements, CLK1 and CLK2 can be chosen different, as long as they are locked to each other with a proper phase relationship. Minimum required single-pole bandwidth at the output for 10-bit precision is  $(10 \ln 2 / 2\pi) \times f_{\text{CLK2}}$ , or approximately  $1.1 f_{\text{CLK2}}$ . In practice,  $< 200$  MHz bandwidth of subsequent circuitry would be sufficient, if  $f_{\text{CLK2}}$  is 100 MHz.

One digital input, Track Mode Select (TMS), is provided to put both TH's in track mode, independent of the clock signals. The bandwidth of the DTH is substantially lower in this mode than in the sampled mode. The TMS is useful for low sample-rate operation, including DC testing.

## Signal Descriptions

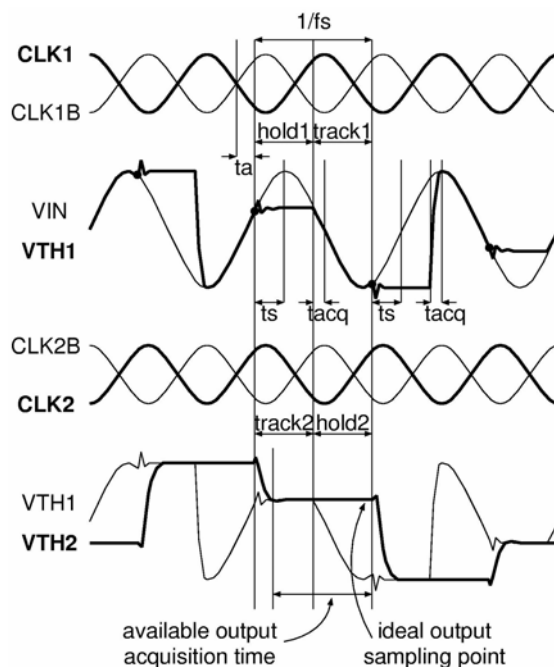

The RTH010 inputs are terminated on-chip with  $50\ \Omega$  to GND. This automatically protects against off-chip high-impedance high-voltage disturbances. The absolute maximum rated voltage at input termination resistors is  $\pm 1\ \text{V}$ , at 20 mA current. The RTH010 is designed for 1 V<sub>pp</sub> differential input signals, and can accept common-mode offsets up to  $\pm 100\ \text{mV}$ . If operated in single-ended mode, terminate the complementary input off-chip with  $50\ \Omega$  to the same common mode as the driven input. The single-ended FSR is half that of the differential FSR. Distortion in the single-ended mode can be up to 6 dB higher than in differential mode, and differential input should be used for optimal performance. The INP and INN inputs are equivalent, except for the polarity of their effect on OUTP and OUTN.

All four clock input signals are terminated on-chip with  $50\ \Omega$  to GND. Use differential clock signals for optimal performance. Large CLK1 edge rate benefits aperture jitter performance, small CLK1 and CLK2 amplitudes minimizes distortion due to clock feed-through in the higher clock frequency range (500 to 1000 MHz). In case of single-ended clocking the complementary

input(s) can be terminated directly to GND (lowest noise, clock waveform distortion is not critical). Distortion for single-ended clocks can be several dB higher than for differential clocks, and differential clocks should be used for optimal performance.

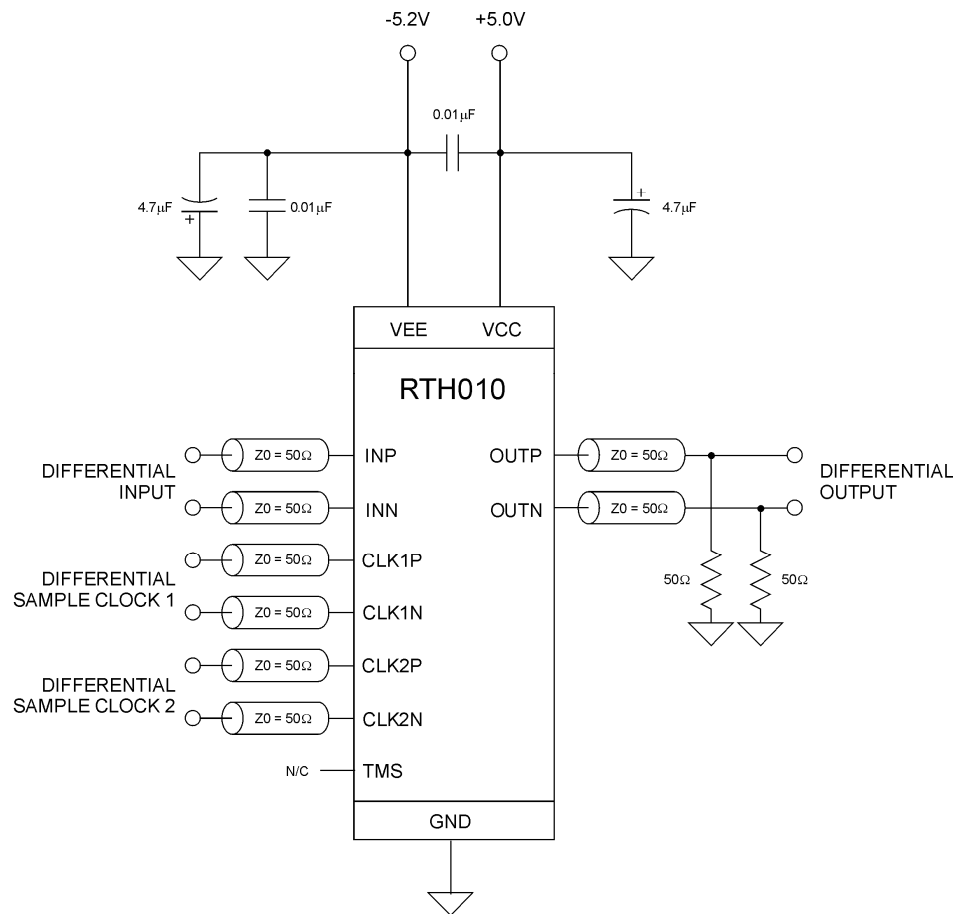

The track-mode select, TMS, can simply be left open for the (default) sampled-mode operation of the RTH010. Grounding the TMS puts both track-and-holds, TH1 and TH2, in track-mode. In this state, the TMS draws up to 0.75 mA of current.

Due to its highly differential design, the RTH010 requires relatively modest power supply decoupling. The  $0.01\ \mu\text{F}$  capacitors VEE to GND and VEE to VCC (Figure 4) should be placed as close to the package as possible. Larger low frequency power supply decoupling capacitors, VEE to GND and VCC to GND, should be placed within 1 inch of the RTH010. Depending on the expected noise on the supplies more capacitors in parallel may need to be used. With low-impedance supplies that are very quiet (no digital circuitry), the RTH010 can also perform well with no external decoupling at all.

### Die Plot and Pad Arrangement

The inputs and output of the RTH010 are arranged in a ground-signal-ground-signal-ground (GSGSG) configuration on opposite sides of the die. The clock signals come in under an orthogonal direction, which

reduces inductive coupling to the signal path, both for bond wires and for package leads. The part does not require other components inside the package, since sufficient bypass capacitance is supplied on-chip.

### Package Information

The package is a 24 lead metallized ceramic base glass sidewall Quad Flat Pack (QFP). The leads are trimmed to 0.150 inch (3.81mm) length. The thermal

impedance (junction to base) is approximately 15 °C/W. The lid is sealed with epoxy.
